Project 2 Robot Code Document

I. Introduction

The basic strategy for this project could be expressed in the following finite state automata (Figure 1).

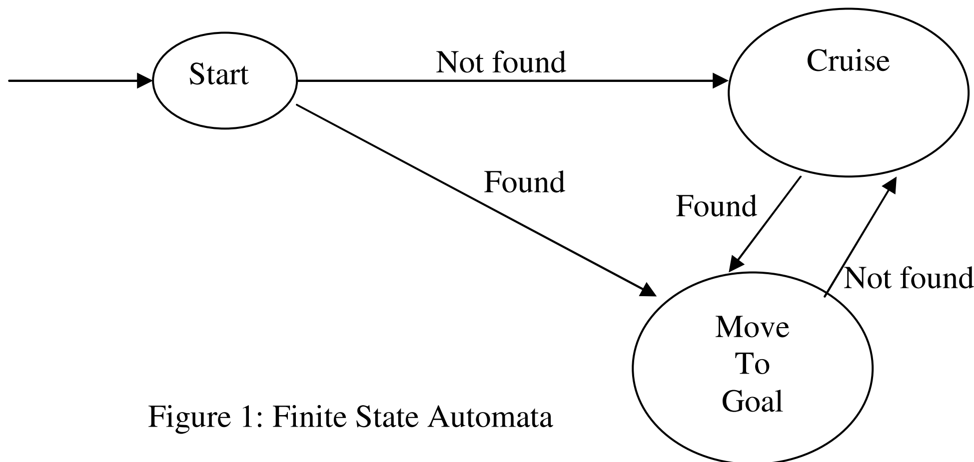

Figure 1: Finite State Automata

The robot started by searching any target that was close enough to it. If a target could be found, it would turn to the target and start moving toward it. Otherwise, it would cruise until it detected a target. During the whole process, the robot would avoid itself from any contact with rocks or hazard objects.

The architecture of the software was based on Schema Theory. It included four main behaviors: **cruise, move to goal, avoid rocks, and avoid hazard objects**. Each behavior consisted of one perceptual schema and one motor schema except for cruise, which only had motor schema (driving forward).

II. Behaviors

1. Move to goal behavior

a. Perceptual Schema: check_light ( )

The robot had four light sensors: two pointing to the front (left front and right front), one pointing to the left, and one pointing to the right. Three variables were set to sense the direction of the target:

- **target_found**: if any reading was lower than a pre-defined value (effective detecting distance), this variable would be set to 1, which meant the target was found by one of the light sensors
- **min**: the minimum reading value of the four sensors
- **direction**: the direction of the minimum reading (part 1, 2, 3 in Figure 2)

Another variable (**delta**) was the difference between two front sensors.

b. Motor Schema: move_to_goal ( )

We divided the view of the robot into three parts (see Figure 2). Only when the **target_found** had been set to 1, the robot would do actions according to the values of other variables.

If the minimum reading was in part 1 or 3, the robot would keep turning left or right until the target entered part 2 (in front of the robot). A **timeout** of 3 seconds was set in order to prevent the robot from turning infinitely in case that the target was blocked when it was turning or simply out of the effective detecting distance.

If the minimum reading was in part 2, delta would be used to adjust the driving direction on its way to the target. A pre-defined value (**delta_thresh**) was used for the sensitivity of the adjustment.

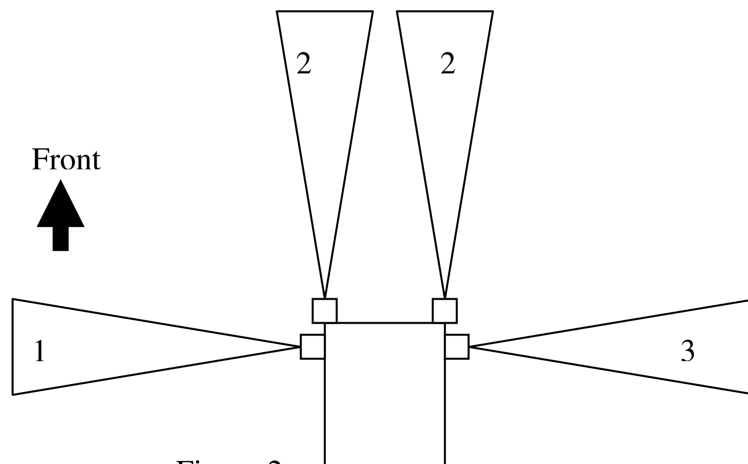

Figure 2

2. Avoid rocks

a. Perceptual schema: check_bumper ( )

Two variables for two touch sensors were used to decide if there was any rock ahead, on the right or the left.

- **left_rock**: set to 1 if left sensor was on
- **right_rock**: set to 1 if right sensor was on

b. Motor schema: avoid_rock ( )

If **left_rock** and **right_rock** were set to 1, the robot would go backward and then take a random turn, either left or right. The turning angle was also random: the sleeping time ranged from 0.3 to 0.9 second. If the **left_rock** were set, the robot would turn to the right; if the **right_rock** were set, turn to the left.

Two counters, **i** and **j**, were used to take a random turn every fourth time when **left_rock** or **right_rock** was set. This was intended to get the robot out of some box canyon situations.

3. Avoid hazard objects

a. Perceptual schema: check_hazobj ( )

This function worked similar to the **check_bumper** except that there was a pre-defined value (**hazobj_min**) used to decide the effective detecting distance to hazard objects.

- **left_haz**: set to 1 if left range finder was within the effective distance
- **right_haz**: set to 1 if right range finder was within the effective distance

Another variable (**hazobj_delta**) was the difference between the readings of two range finders.

b. Motor schema: avoid_hazobj ( )

If both **left_haz** and **right_haz** were set, the robot would take a turn and the direction would depend on the **hazobj_delta**. Otherwise, if only **left_haz** or **right_haz** was set, the robot would take a right or left turn, respectively. Turning angles were random angles similar to **avoid_rock**.

4. Flag variables (avoid_rock_flag, avoid_hazobj_flag, move_to_goal_flag)

The robot wouldn't cruise if it was driving backward or taking turns. The purpose of using these flag variables was to disable/enable the cruise function (driving forward) when the robot was avoiding rocks/hazard objects or deciding which direction should turn.

III. Problems and solutions

The robot run pretty well as we expected. Many problems, such as being stuck by rocks, cable, and so on, mainly because of the construction of robot's bumper. Other software problems were solved during four demos:

1. The balance between attractive force from the target and repulsive forces from obstacles: in order to get the robot out of local minima, in which the summation of forces would cause the robot to keep doing some repetitive things in a very small area

and couldn't move any closer toward the target. Our solution was to use random turning angles, random turning directions, and smaller effective detection distance.

Another very important solution was to make sure the sleeping time after the adjustment of **move_to_goal** was large enough to give the robot enough time to complete the action of avoiding rocks. We met this case in our first demo.

2. Prevent robot from touching hazard object after it turned off the light and moved backward. A similar case would happen when robot was walking between two or more hazard objects. Our solution was to decrease the sleeping time for backward but still keep it large enough so that the robot wouldn't hit hazard object when it turned. It turned out the robot could walk among two hazard objects and some other obstacles that were pretty close to each other, and didn't touch any hazard objects.
